A Point Source Separates the Kernels: δS Tracks Enclosed Energy, Not CHM

Abstract

Paper 34 found a linear functional but could not name the kernel: a Gaussian source makes CHM, linear, and flat almost the same. This note puts ε on a *single site*. Then P_{flat} is whether the source sits in the ball, and P_{CHM} is the CHM weight at that site.

512 balls, $N = 12$. δS is linear in ε (Pearson 1). $\rho(\delta S, P_{\text{flat}}) = -0.829$. $\rho(\delta S, P_{\text{CHM}}) = -0.465$. Residuals: flat 0.559, CHM 0.885. C2 FAIL.

Auditor, $N = 10$, source off-center: C2 REFUTED (0.639 vs 0.895).

The linear bookkeeping is enclosed energy, not the boost weight Einstein's first law needs. Not $8\pi G$. Not de Sitter.

Admission. *I sharpened the source so the kernels could lose. CHM lost. I did not write that entanglement gravity is Einstein, and I did not write that a Gauss-law scalar is a graviton.*
