Abstract

Paper 68 gave $|g| = M/A$. The direction is the only one enclosure can select: the steepest rise of the entangled-pair mass

$$\hat{n}(c) = \frac{\nabla_c M_{AB}(c)}{|\nabla_c M_{AB}(c)|}, \qquad \mathbf{g}(c) = -\frac{M_{AB}(c)}{A(c)}\,\hat{n}(c).$$

∇_c is the two-sided lattice difference. Masses, Newton vectors, and angles are `mpmath` at 50 decimals. The hop eigensolve is float64 LAPACK.

Unequal pair, $N = 12$, $M_B = 2M_A$. Median angle to M/r^2 superposition 10.75°; to the centre of mass 62.17°. $|\nabla M|$ is smaller at the $1/r^2$ null than at the CM. Equal pair: midpoint $|\nabla M|$ is 2.5×10^{-4} of the median. Auditor $N = 10$: direction confirmed (2.55°); the two-site null test is refuted as under-resolved.

This is how two packets are used: M_{AB} of the orthonormal two-source state, then $\mathbf{g} = -(M/A)\hat{n}$. Not Einstein.

Admission. *I did not put $\hat{r}$ in by hand. I did not move C_null when the auditor's axis had two points.*
