

Dust, Not Λ .

The Slope Interpolates. The Force Is Inward.

Abstract

Paper 54 called a uniform positive δe a Newtonian Λ signature. That was the wrong sign. $a = -(4\pi G\rho/3)r$ is a ball of dust. $a = +(\Lambda/3)r$ is de Sitter. Occupation transfer on the Fermi sea always raises $\langle H \rangle$. There is no negative-energy sea here.

First-law Gauss, $N = 12$. Slope of $|a|$ vs R : $\sigma = 1 \rightarrow -1.868$; $\sigma = 2 \rightarrow -0.903$; $\sigma = 4 \rightarrow +0.404$; $\sigma = 8 \rightarrow +1.001$; periodic sea $\rightarrow +1.266$. Every $a(R)$ is inward.

Auditor, $N = 10$: $-1.837 \rightarrow +0.601$, inward CONFIRMED, monotone CONFIRMED.

The instrument interpolates. The force is dust. I withdraw “Newtonian Λ ”.

Admission. *I named the sea Λ and I had the sign wrong. Every a in this instrument points in. That is not de Sitter.*
