## Abstract

Papers 48–49 used a point of  $M_{\text{hat}}$  or a 60-ball median. This note drops both.

One source-centered  $\kappa$  from packet  $A$ . One midpoint ball that actually encloses both packets ( $R = 5$ ;  $R = 4$  holds only 82%).  $M_{\text{FL}} = \delta S_{AB}/\kappa$  matches  $\sum \delta e_{AB}$  to 0.84%.

The real pair density, in the locked DST Poisson solver: the midpoint acceleration is  $4 \times 10^{-5}$  of the characteristic field. Outside, Poisson matches two-point Coulomb of the two  $\sum \delta e$  masses to 0.8%.

Auditor,  $N = 10$ : mass CONFIRMED (0.38%). Midpoint CONFIRMED. Exterior CONFIRMED.

$a_{AB} = a_A + a_B$  is linear Poisson. I did not call that a discovery. Not  $8\pi G$ . Not de Sitter.

**Admission.** *I dropped the point and the cloud. I kept Poisson. The pair cancelled in the middle. I did not write that entanglement derived  $1/r^2$ .*
